Indexes Part 2 and Query Execution

Instructor: Matei Zaharia

cs245.stanford.edu

From Last Time: Indexes

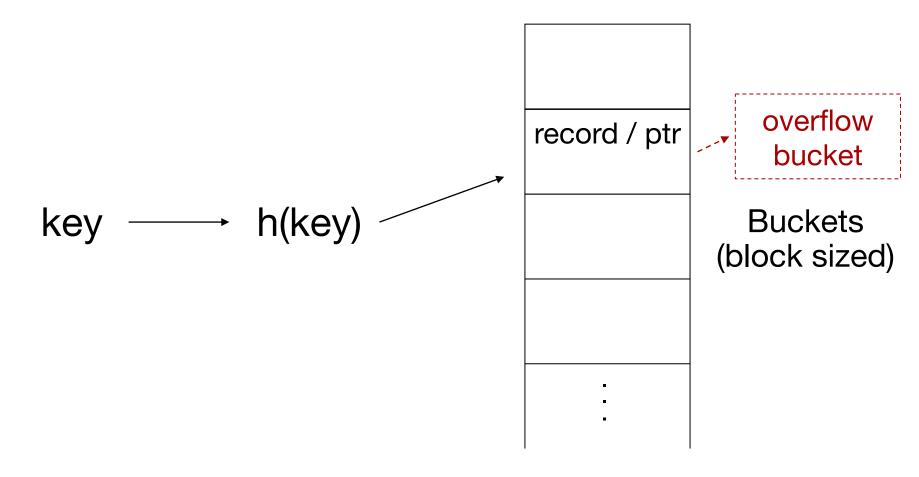

Conventional indexes

B-trees

Hash indexes

Multi-key indexing

Hash Indexes

Chaining is used to handle bucket overflow

Hash vs Tree Indexes

- + O(1) instead of O(log N) disk accesses
- Can't efficiently do range queries

Challenge: Resizing

Hash tables try to keep occupancy in a fixed range (50-80%) and slow down beyond that

» Too much chaining

How to resize the table when this happens?

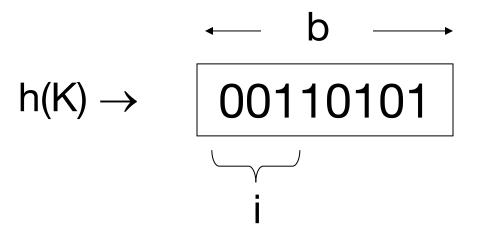

- » In memory: just move everything, amortized cost is pretty low
- » On disk: moving everything is expensive!

Extendible Hashing

Tree-like design for hash tables that allows cheap resizing while requiring 2 IOs / access

Extendible Hashing: 2 Ideas

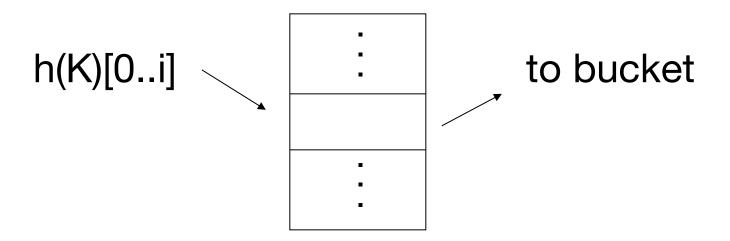

(a) Use i of b bits output by hash function

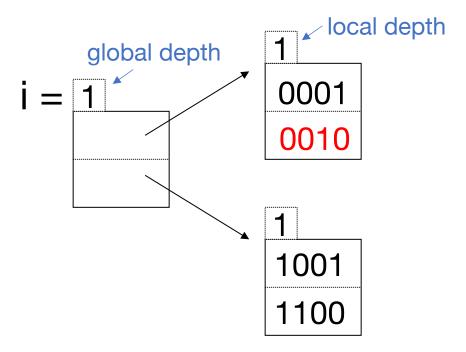

i will grow over time; the first i bits of each key's hash are used to map it to a bucket

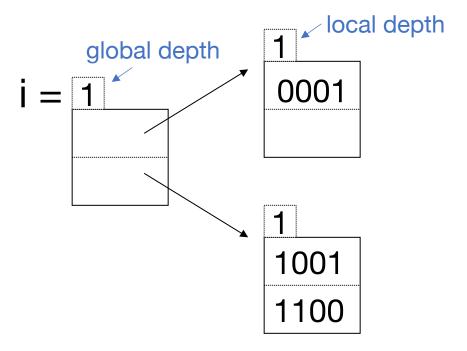

Extendible Hashing: 2 Ideas

(b) Use a directory with pointers to buckets

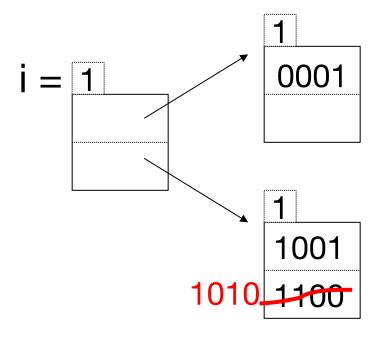

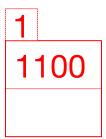

Insert 0010

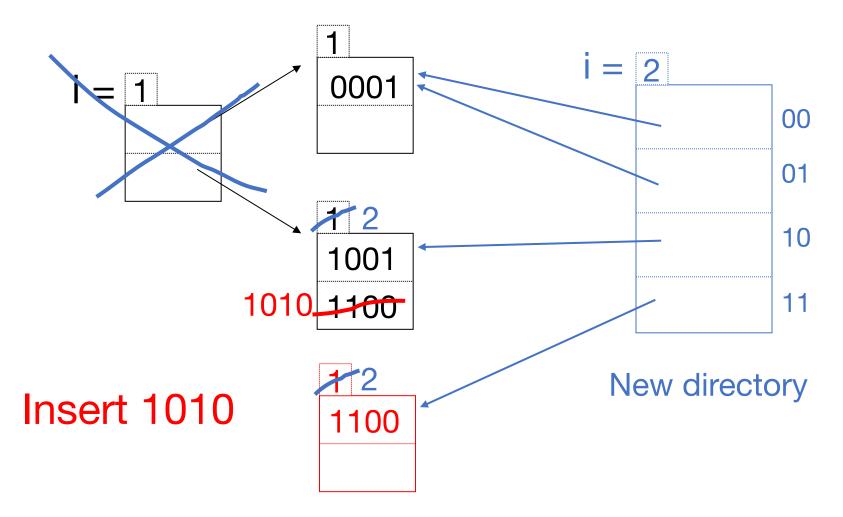

Insert 1010

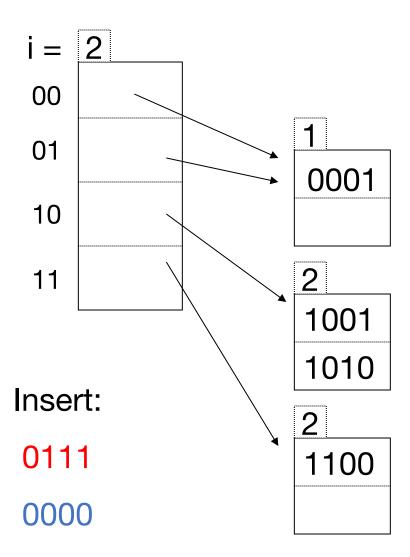

Insert 1010

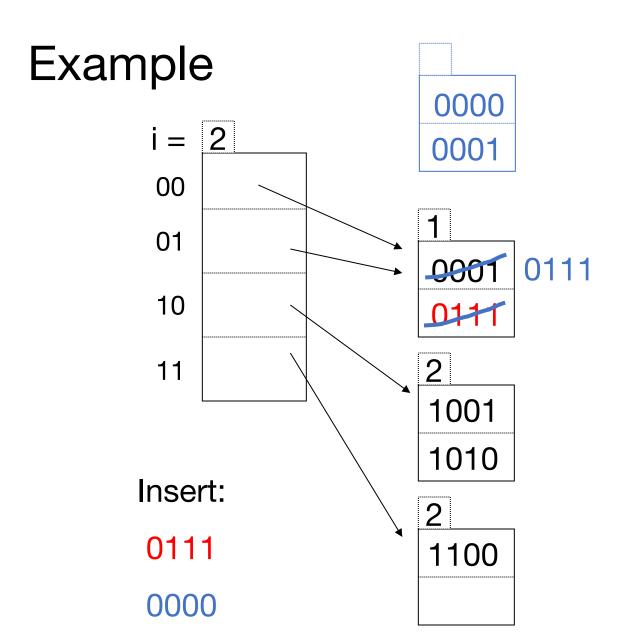

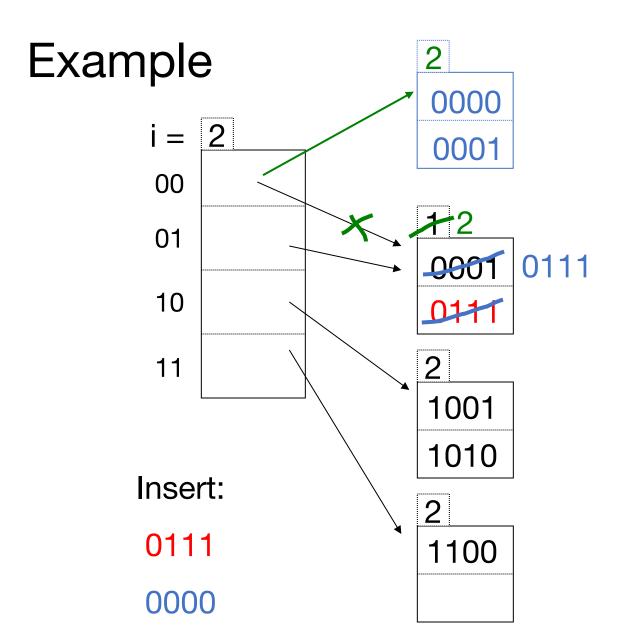

Example

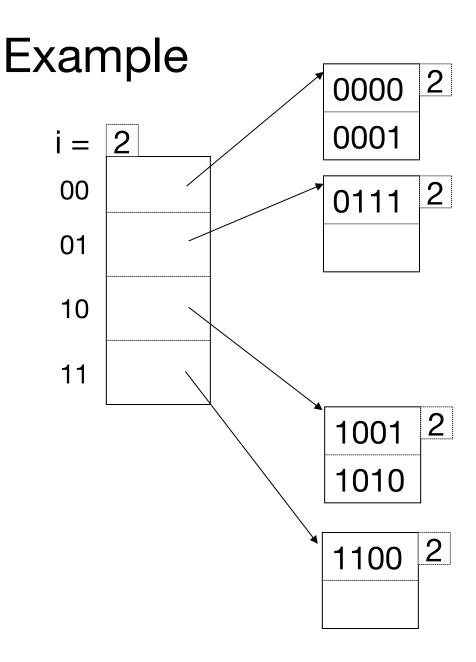

CS 245

13

Note: still need chaining if values of h(K) repeat and fill a bucket

CS 245

16

Some Types of Indexes

Conventional indexes

B-trees

Hash indexes

Multi-key indexing

Motivation

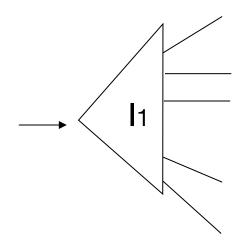

Example: find records where

DEPT = "Toy" AND SALARY > 50k

Strategy I:

Use one index, say Dept.

Get all Dept = "Toy" records and check their salary

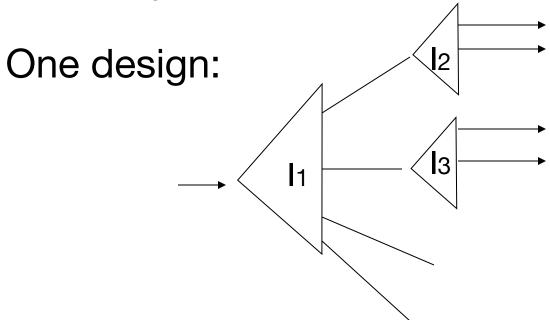

Strategy II:

Use 2 indexes; intersect lists of pointers

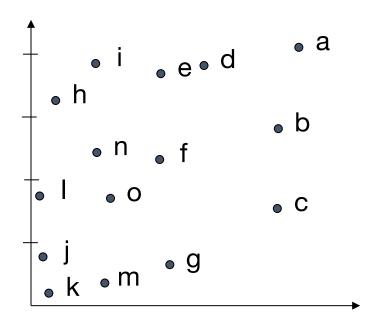

Strategy III:

Multi-key index

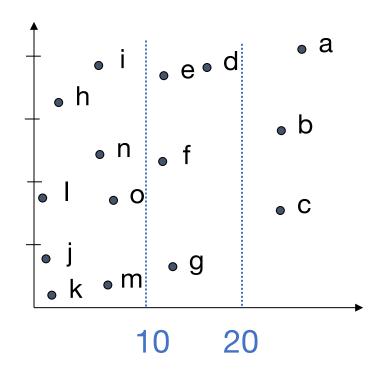

k-d Trees

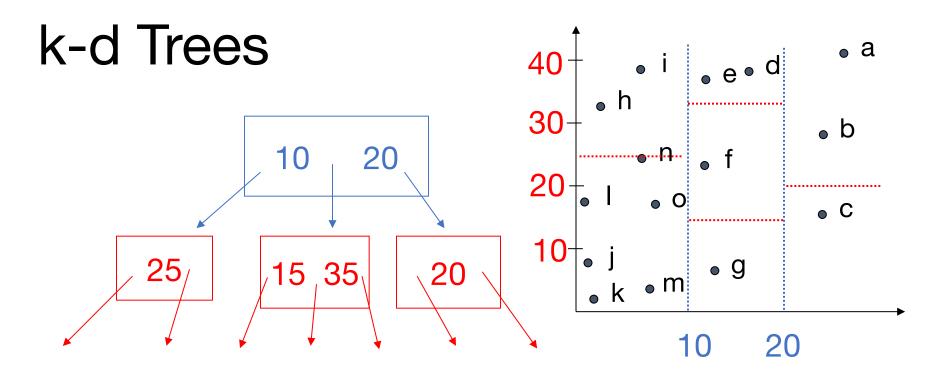

Split dimensions in any order to hold k-dimensional data

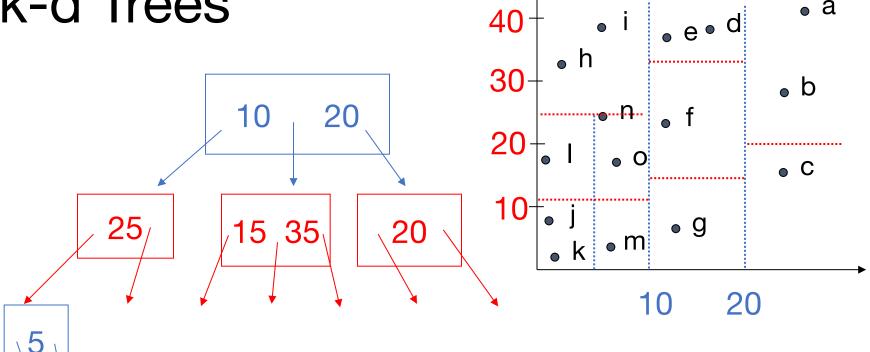

k-d Trees

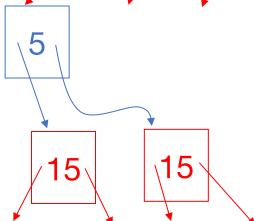

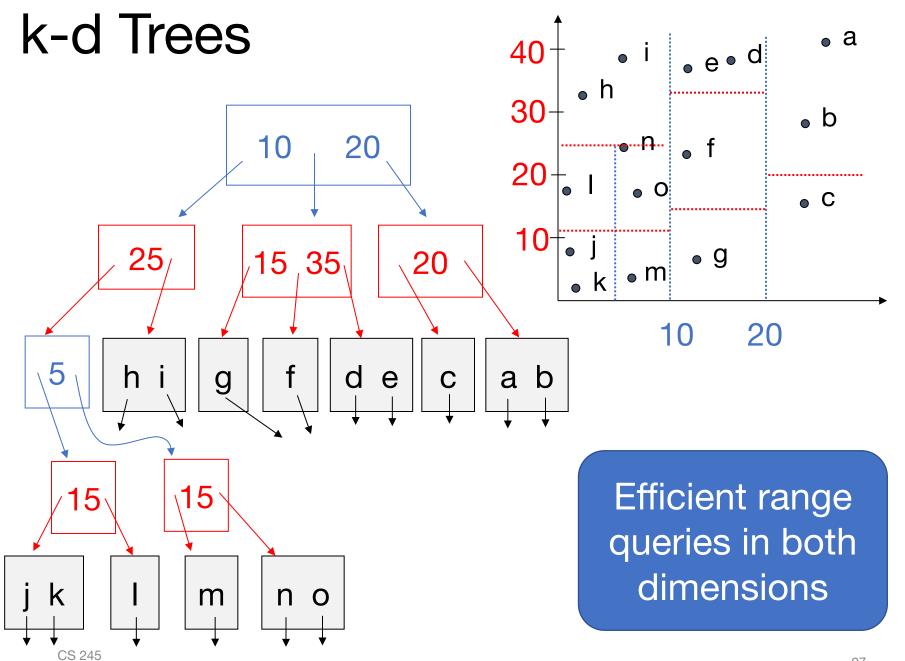

CS 245

26

Storage System Examples

MySQL: transactional DBMS

- » Row-oriented storage with 16 KB pages
- » Variable length records with headers, overflow
- » Index types:
 - B-tree
 - Hash (in memory only)
 - R-tree (spatial data)
 - Inverted lists for full text search
- » Can compress pages with Lempel-Ziv

Storage System Examples

Apache Parquet + Hive: analytical data lake

- » Column-oriented storage as set of ~1 GB files (each file has a slice of all columns)
- » Various compression and encoding schemes at the level of pages in a file
 - Special scheme for nested fields (Dremel)
- » Header with statistics at the start of each file
 - Min/max of columns, nulls, Bloom filter
- » Files partitioned into directories by one key

Query Execution

Overview

Relational operators

Execution methods

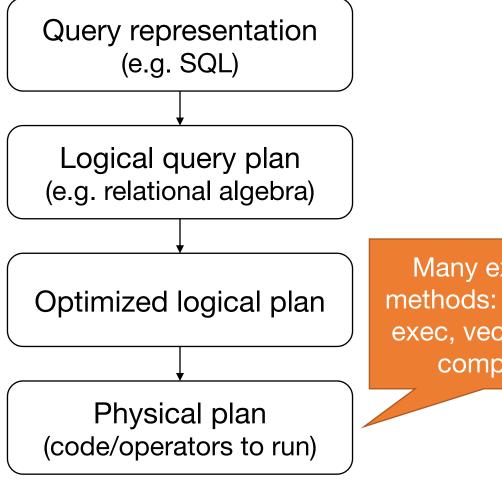

Query Execution Overview

Recall that one of our key principles in data intensive systems was **declarative APIs**» Specify what you want to compute, not how

We saw how these can translate into many storage strategies

How to execute queries in a declarative API?

Query Execution Overview

Many execution methods: per-record exec, vectorization, compilation

Plan Optimization Methods

Rule-based: systematically replace some expressions with other expressions

- » Replace X OR TRUE with TRUE
- » Replace M*A + M*B with M*(A+B) for matrices

Cost-based: propose several execution plans and pick best based on a cost model

Adaptive: update execution plan at runtime

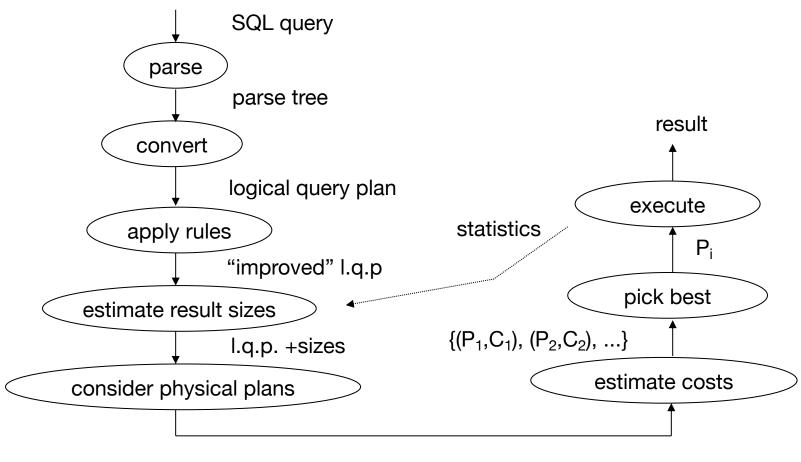

Execution Methods

Interpretation: walk through query plan operators for each record

Vectorization: walk through in batches

Compilation: generate code (like System R)

Typical RDBMS Execution

 $\{P_1, P_2, ...\}$

Query Execution

Overview

Relational operators

Execution methods

The Relational Algebra

Collection of operators over tables (relations) » Each table has named attributes (fields)

Codd's original RA: tables are **sets of tuples** (unordered and tuples cannot repeat)

SQL's RA: tables are **bags** (multisets) of **tuples**; unordered but each tuple may repeat

Basic set operators:

Intersection: R ∩ S

Union: R∪S

Difference: R - S

for tables with same schema

Cartesian Product: $R \times S \{ (r, s) | r \in R, s \in S \}$

Basic set operators:

Intersection: R ∩ S

Union: R ∪ S ← consider both distinct (set union) and non-distinct (bag union)

Difference: R – S

Cartesian Product: R × S

Special query processing operators:

```
Selection: \sigma_{condition}(R) { r \in R \mid condition(r) \text{ is true }}
```

```
Projection: \Pi_{\text{expressions}}(R) { expressions(r) | r ∈ R }
```

Natural Join: $R \bowtie S$ { $(r, s) \in R \times S) \mid r.key = s.key } where key is the common fields$

Special query processing operators:

Aggregation: keys Gagg(attr)(R)

SELECT agg(attr) FROM R GROUP BY keys

Examples: department G_{Max(salary)} (Employees)

G_{Max(salary)}(Employees)

Algebraic Properties

Many properties about which combinations of operators are equivalent

» That's why it's called an algebra!

Properties: Unions, Products and Joins

$$R \cup S = S \cup R$$

 $R \cup (S \cup T) = (R \cup S) \cup T$

doesn't matter either

Tuple order in a relation

doesn't matter (unordered)

$$R \times S = S \times R$$

 $(R \times S) \times T = R \times (S \times T)$

$$R \bowtie S = S \bowtie R$$

 $(R \bowtie S) \bowtie T = R \bowtie (S \bowtie T)$

Properties: Selects

$$\sigma_{p \wedge q}(R) =$$

$$\sigma_{pvq}(R) =$$

Properties: Selects

$$\sigma_{p \wedge q}(R) = \sigma_p(\sigma_q(R))$$

$$\sigma_{p \vee q}(R) = \sigma_p(R) \cup \sigma_q(R)$$

careful with repeated elements

Bags vs. Sets

 $R = \{a,a,b,b,b,c\}$

 $S = \{b,b,c,c,d\}$

 $R \cup S = ?$

Bags vs. Sets

```
R = \{a,a,b,b,b,c\}
S = \{b,b,c,c,d\}
R \cup S = ?
```

- Option 1: SUM of counts
 R U S = {a,a,b,b,b,b,c,c,c,d}
- Option 2: MAX of counts
 R ∪ S = {a,a,b,b,b,c,c,d}

Executive Decision

Use "SUM" option for bag unions

Some rules that work for set unions cannot be used for bags

Properties: Project

Let: X = set of attributes

Y = set of attributes

$$\Pi_{X \cup Y}$$
 (R) =

Properties: Project

Let: X = set of attributes

Y = set of attributes

$$\Pi_{X \cup Y}(R) = \Pi_X(\Pi_Y(R))$$

Properties: Project

Let: X = set of attributes

Y = set of attributes

$$\Pi_{X \cup Y}(R) = \Pi_X(R_X(R))$$

Let p = predicate with only R attribs

q = predicate with only S attribs

m = predicate with only R, S attribs

$$\sigma_{p}(R \bowtie S) =$$

$$\sigma_{q}(R \bowtie S) =$$

Let p = predicate with only R attribs

q = predicate with only S attribs

m = predicate with only R, S attribs

$$\sigma_p(R \bowtie S) = \sigma_p(R) \bowtie S$$

$$\sigma_{q}(R \bowtie S) = R \bowtie \sigma_{q}(S)$$

Some rules can be derived:

$$\sigma_{p \wedge q}(R \bowtie S) =$$

$$\sigma_{p \land q \land m}(R \bowtie S) =$$

$$\sigma_{pvq}(R \bowtie S) =$$

Some rules can be derived:

$$\sigma_{p \wedge q}(R \bowtie S) = \sigma_p(R) \bowtie \sigma_q(S)$$

$$\sigma_{p \land q \land m}(R \bowtie S) = \sigma_m(\sigma_p(R) \bowtie \sigma_q(S))$$

$$\sigma_{p\vee q}(R\bowtie S)=(\sigma_p(R)\bowtie S)\cup (R\bowtie \sigma_q(S))$$

Prove One, Others for Practice

$$\sigma_{p \wedge q}(R \bowtie S) = \sigma_{p} (\sigma_{q}(R \bowtie S))$$

$$= \sigma_{p} (R \bowtie \sigma_{q}(S))$$

$$= \sigma_{p} (R) \bowtie \sigma_{q}(S)$$

Properties: $\Pi + \sigma$

Let x =subset of R attributes

z = attributes in predicate p (subset of R attributes)

$$\Pi_{x}(\sigma_{p}(R)) =$$

Properties: $\Pi + \sigma$

Let x =subset of R attributes

z = attributes in predicate p (subset of R attributes)

$$\Pi_{x}(\sigma_{p}(R)) = \sigma_{p}(\Pi_{x}(R))$$

Properties: $\Pi + \sigma$

Let x =subset of R attributes

z = attributes in predicate p (subset of R attributes)

$$\Pi_{x}(\sigma_{p}(R)) = \Pi_{x}(\sigma_{p}(\Pi_{x \cup z}(R)))$$

Let x =subset of R attributes

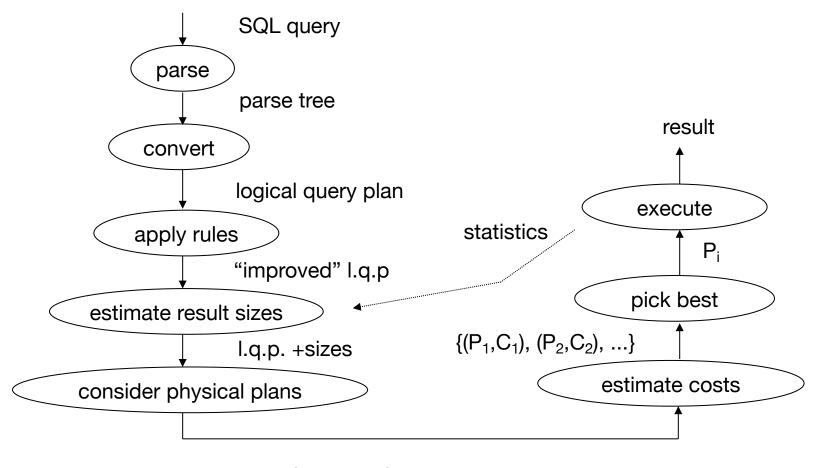

y = subset of S attributes

z = intersection of R,S attributes

$$\Pi_{x \cup y}(R \bowtie S) = \Pi_{x \cup y}((\Pi_{x \cup z}(R)) \bowtie (\Pi_{y \cup z}(S)))$$

61

Typical RDBMS Execution

 $\{P_1, P_2, ...\}$

Example SQL Query

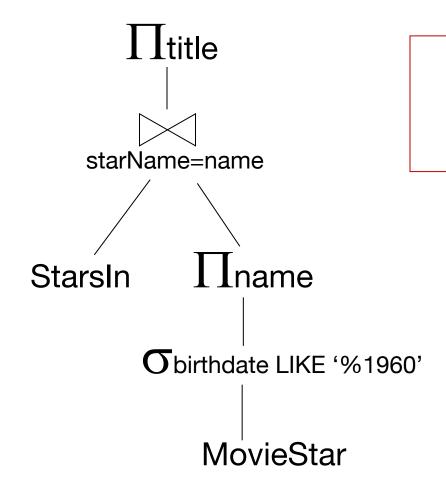

(Find the movies with stars born in 1960)

Parse Tree <Query> <SFW> WHERE FROM <FromList> <Condition> SELECT <SelList> <Tuple> IN <Query> <RelName> <Attribute> title StarsIn <Attribute> (<Query>) starName ≤SFW> FROM <FromList> <SelList> WHERE SELECT <Condition> <Attribute> LIKE <Pattern> <RelName> <Attribute> MovieStar birthDate **'%1960'** name

Logical Query Plan

Improved Logical Query Plan

Query Execution

Overview

Relational operators

Execution methods

Now That We Have a Plan, How Do We Run it?

Several different options that trade between complexity, setup time & performance

Example: Simple Query

```
SELECT quantity * price
FROM orders
WHERE productId = 75
```

$$\Pi_{\text{quanity*price}} (\sigma_{\text{productId=75}} (\text{orders}))$$

Method 1: Interpretation

```
interface Expression {
interface Operator {
                                  Value compute(Tuple in);
  Tuple next();
                                class Attribute: Expression {
class TableScan: Operator {
 String tableName;
                                  String name;
                                class Times: Expression {
class Select: Operator {
                                  Expression left, right;
 Operator parent;
  Expression condition;
                                class Equals: Expression {
                                  Expression left, right;
class Project: Operator {
 Operator parent;
  Expression[] exprs;
```

Example Expression Classes

```
class Attribute: Expression {
                                   probably better to use a
  String name;
                                   numeric field ID instead
 Value compute(Tuple in) {
    return in.getField(name);
class Times: Expression {
  Expression left, right;
 Value compute(Tuple in) {
    return left.compute(in) * right.compute(in);
```

Example Operator Classes

```
class TableScan: Operator {
 String tableName;
 Tuple next() {
    // read & return next record from file
class Project: Operator {
 Operator parent;
 Expression[] exprs;
 Tuple next() {
    tuple = parent.next();
    fields = [expr.compute(tuple) for expr in exprs];
    return new Tuple(fields);
```

Running Our Query with Interpretation

```
ops = Project(
       expr = Times(Attr("quantity"), Attr("price")),
       parent = Select(
         expr = Equals(Attr("productId"), Literal(75)),
         parent = TableScan("orders")
                           recursively calls Operator.next()
while(true) {
                           and Expression.compute()
  Tuple t = ops.next();
  if (t != null) {
   out.write(t);
  } else {
                                  Pros & cons of this
   break;
                                       approach?
```

Method 2: Vectorization

Interpreting query plans one record at a time is simple, but it's too slow

» Lots of virtual function calls and branches for each record (recall Jeff Dean's numbers)

Keep recursive interpretation, but make Operators and Expressions run on **batches**

Implementing Vectorization

```
class ValueBatch {
class TupleBatch {
  // Efficient storage, e.g.
                                  // Efficient storage
  // schema + column arrays
                                interface Expression {
                                  ValueBatch compute(
interface Operator {
                                    TupleBatch in);
  TupleBatch next();
class Select: Operator {
                                class Times: Expression {
                                  Expression left, right;
  Operator parent;
  Expression condition;
```

Typical Implementation

Values stored in columnar arrays (e.g. int[]) with a separate bit array to mark nulls

Tuple batches fit in L1 or L2 cache

Operators use SIMD instructions to update both values and null fields without branching

Pros & Cons of Vectorization

- + Faster than record-at-a-time if the query processes many records
- + Relatively simple to implement
- Lots of nulls in batches if query is selective
- Data travels between CPU & cache a lot

Method 3: Compilation

Turn the query into executable code

Compilation Example

 $\Pi_{\text{quanity*price}} (\sigma_{\text{productId=75}} (\text{orders}))$

```
generated class with the right
class MyQuery {
    void run() {
        Iterator<OrdersTuple> in = openTable("orders");
        for(OrdersTuple t: in) {
            if (t.productId == 75) {
                out.write(Tuple(t.quantity * t.price));
            }
        }
    }
}
```

Can also theoretically generate vectorized code

Pros & Cons of Compilation

- + Potential to get fastest possible execution
- + Leverage existing work in compilers
- Complex to implement
- Compilation takes time
- Generated code may not match hand-written

What's Used Today?

Depends on context & other bottlenecks

Transactional databases (e.g. MySQL): mostly record-at-a-time interpretation

Analytical systems (Vertica, Spark SQL): vectorization, sometimes compilation

ML libs (TensorFlow): mostly vectorization (the records are vectors!), some compilation
